OVERVIEW

The VT8235 South Bridge is a high integration, high performance, power-efficient, and high compatibility device that supports Intel and non-Intel based processor to V-Link bus bridge functionality to make a complete Microsoft PC2001-compliant PCI/LPC system. The VT8235 includes standard intelligent peripheral controllers:

a) IEEE 802.3 compliant 10 / 100 Mbps PCI bus master Ethernet MAC with standard MII interface to external PHYceiver.

b) Master mode enhanced IDE controller with dual channel DMA engine and interlaced dual channel commands. Dedicated FIFO coupled with scatter and gather master mode operation allows high performance transfers between PCI and IDE devices. In addition to standard PIO and DMA mode operation, the VT8235 also supports the UltraDMA-133, 100, 66, and 33 standards to allow reliable data transfer at rates up to 133 MB/sec. The IDE controller is SFF-8038i v1.0 and Microsoft Windows-family compliant.

c) Universal Serial Bus controller that is USB v2.0 / 1.1 and Universal HCI v2.0 / 1.1 compliant. The VT8235 includes three root hubs with six function ports with integrated physical layer transceivers. The USB controller allows hot plug and play and isochronous peripherals to be inserted into the system with universal driver support. The controller also implements legacy keyboard and mouse support so that legacy software can run transparently in a non-USB-aware operating system environment.

d) Keyboard controller with PS2 mouse support.

e) Real Time Clock with 256 byte extended CMOS. In addition to the standard ISA RTC functionality, the integrated RTC also includes the date alarm, century field, and other enhancements for compatibility with the ACPI standard.

f) Notebook-class power management functionality compliant with ACPI and legacy APM requirements. Multiple sleep states (power-on suspend, suspend-to-DRAM, and suspend-to-Disk) are supported with hardware automatic wake-up. Additional functionality includes event monitoring, CPU clock throttling and stop (Intel processor protocol), PCI bus clock stop control, modular power, clock and leakage control, hardware-based and software-based event handling, general purpose I/O, chip select and external SMI.

g) Full System Management Bus (SMBus) interface.

h) Integrated bus-mastering dual full-duplex direct-sound AC97-link-compatible sound system.

i) Plug and Play controller that allows complete steerability of all PCI interrupts and internal interrupts / DMA channels to any interrupt channel. One additional steerable interrupt channel is provided to allow plug and play and reconfigurability of on-board peripherals for Windows family compliance.

The VT8235 also enhances the functionality of the standard ISA peripherals. The integrated interrupt controller supports both edge and level triggered interrupts channel by channel. The integrated DMA controller supports type F DMA in addition to standard ISA DMA modes. Compliant with the PCI-2.2 specification, the VT8235 supports delayed transactions and remote power management so that slower ISA peripherals do not block the traffic of the PCI bus. Special circuitry is built in to allow concurrent operation without causing dead lock even in a PCI-to-PCI bridge environment. The chip also includes eight levels (doublewords) of line buffers from the PCI bus to the ISA bus to further enhance overall system performance.

REGISTERS

Register Overview

The following tables summarize the configuration and I/O registers of the VT8235. These tables also document the power-on default value ("Default") and access type ("Acc") for each register. Access type definitions used are RW (Read/Write), RO (Read/Only), "—" for reserved / used (essentially the same as RO), and RWC (or just WC) (Read / Write 1's to Clear individual bits). Registers indicated as RW may have some read/only bits that always read back a fixed value (usually 0 if unused); registers designated as RWC or WC may have some read-only or read write bits (see individual register descriptions for details).

Detailed register descriptions are provided in the following section of this document. All offset and default values are shown in hexadecimal unless otherwise indicated

Register Descriptions

Legacy I/O Ports

This group of registers includes the DMA Controllers, Interrupt Controllers, and Timer/Counters as well as a number of miscellaneous ports originally implemented using discrete logic on original PC/AT motherboards. All of the registers listed are integrated on-chip. These registers are implemented in a precise manner for backwards compatibility with previous generations of PC hardware. These registers are listed for information purposes only. Detailed descriptions of the actions and programming of these registers are included in numerous industry publications (duplication of that information here is beyond the scope of this document). All of these registers reside in I/O space.

Port 61 - Misc Functions & Speaker Control ..... RW

7 SERR# Status.....RO
- 0 SERR# has not been asserted.....default
- 1 SERR# was asserted by a PCI agent

Note: This bit is set when the PCI bus SERR# signal is asserted. Once set, this bit may be cleared by setting bit-2 of this register. Bit-2 should be cleared to enable recording of the next SERR# (i.e., bit-2 must be set to 0 to enable this bit to be set).

6 IOCHK# Status.....RO
- 0 IOCHK# has not been asserted.....default
- 1 IOCHK # was asserted by an ISA agent

Note: This bit is set when the ISA bus IOCHCK# signal is asserted. Once set, this bit may be cleared by setting bit-3 of this register. Bit-3 should be cleared to enable recording of the next IOCHCK# (i.e., bit-3 must be set to 0 to enable this bit to be set). IOCHCK# generates NMI to the CPU if NMI is enabled.

5 Timer/Counter 2 Output.....RO
This bit reflects the output of Timer/Counter 2 without any synchronization.

4 Refresh Detected.....RO
This bit toggles on every rising edge of the ISA bus REFRESH# signal.

3 IOCHK# Enable
- 0 Enable (see bit-6 above) .....default
- 1 Disable (force IOCHCK# inactive and clear any “IOCHCK# Active” condition in bit-6)

2 SERR# Enable
- 0 Enable (see bit-7 above) .....default
- 1 Disable (force SERR# inactive and clear any “SERR# Active” condition in bit-7)

1 Speaker Enable
- 0 Disable.....default
- 1 Enable Timer/Ctr 2 output to drive SPKR pin

0 Timer/Counter 2 Enable
- 0 Disable.....default
- 1 Enable Timer/Counter 2

Port 92h - System Control..... RW

7-2 Reserved .....always reads 0

1 A20 Address Line Enable
- 0 A20 disabled / forced 0 (real mode) .....default
- 1 A20 address line enabled

0 High Speed Reset
- 0 Normal
- 1 Briefly pulse system reset to switch from protected mode to real mode

Keyboard Controller I/O Registers

The keyboard controller handles the keyboard and mouse interfaces. Two ports are used: port 60 and port 64. Reads from port 64 return a status byte. Writes to port 64h are command codes (see command code list following the register descriptions). Input and output data is transferred via port 60.

A "Control" register is also available. It is accessable by writing commands 20h / 60h to the command port (port 64h); The control byte is written by first sending 60h to the command port, then sending the control byte value. The control register may be read by sending a command of 20h to port 64h, waiting for "Output Buffer Full" status = 1, then reading the control byte value from port 60h.

Traditional (non-integrated) keyboard controllers have an "Input Port" and an "Output Port" that control pins dedicated to specific functions. In the integrated version, connections are hard wired as listed below. Outputs are "open-collector" so to allow input on one of these pins, the output value for that pin would be set high (non-driving) and the desired input value read on the input port. These ports are defined as follows:

Bit	Input Port
0	Keyboard Data In
1	Mouse Data In

Bit	Output Port
0	System Reset (1 = Execute Reset)
1	Gaste A20 (1 = A20 Enabled)
2	Mouse Data Out
3	Mouse Clock Out
6	Keyboard Clock Out

Keyboard / Mouse Wakeup Index / Data Registers

7 USB 1.1 Improvement for EOP

This bit controls whether USB Specification 1.1 or 1.0 is followed when a stuffing error occurs before an EOP (End-Of-Packet). A stuffing error results when the receiver sees seven consecutive ones in a packet. Under USB specification 1.1, when this occurs in the interval just before an EOP, the receiver will accept the packet. Under USB specification 1.0, the packet is ignored.

1 A20Gate Pass Through Option

Offset 42 – Line Buffer Control (00h)..... RW

7 ISA Master DMA Line Buffer
Controls whether the DMA line buffer is used.

Offset 85-84 - Primary Interrupt Channel (0000h) .....RW

If a device IRQ is enabled as a Primary IRQ, that device's IRQ can be used to generate wake events. The bits in this register are used in conjunction with:

- PMIO Rx28[7] – Primary Resume Status
- PMIO Rx2A[7] – Primary Resume Enable

If a device on one of the IRQ's is set to enable the Primary Interrupt, once the device generates an IRQ, the PMIO Rx28[7] status bit will become 1 to report the occurrence of the Primary IRQ. If PMIO Rx2A[7] is set to 1 to enable Resume-on-Primary-IRQ, the IRQ then becomes a wake event.

Offset 87-86 - Secondary Interrupt Channel (0000h) .... RW

For legacy PMU, the bits in this register are used in conjunction with:

- PMIO Rx28[1] – Secondary Event Timer Timeout Status
- PMIO Rx2A[7] – SMI on Secondary Event Timer Timeout

Secondary IRQ's are different from Primary IRQ's in that systems that resume due to a Secondary IRQ can return directly to suspend state after the secondary event timer times out. For this to work, PMIO Rx2A[1] needs to be set to one to enable SMI-on-Secondary-Event-Timer-Timeout (when PMIO Rx28[1] = 1). The timer's count value can be set via Rx93-90[27-26].

7-4 Thermal Duty Cycle
This field determines the duty cycle of STPCLK# when the THRM# pin is asserted. The duty cycle indicates the percentage of performance (the lower the percentage, the lower the performance and the higher the power savings). The STPCLK# duty cycle when THRM# is NOT asserted is controlled by PMIO Rx10[3:0]. If the setting in that field is lower than the setting in this field, the lower setting will be used for thermal duty cycle.

Power Management I/O-Space Registers

Basic Power Management Control and Status

I/O Offset 1-0 - Power Management Status .....RWC

The bits in this register are set only by hardware and can be reset by software by writing a one to the desired bit position.

15 **Wakeup Status** ..... default = 0
This bit is set when the system is in the suspend state and an enabled resume event occurs. Upon setting this bit, the system automatically transitions from the suspend state to the normal working state (from C3 to C0 for the processor).

14-12 **Reserved** ..... always reads 0

11 **Abnormal Power-Off Status** ..... default = 0

10 **RTC Alarm Status** ..... default = 0
This bit is set when the RTC generates an alarm (on assertion of the RTC IRQ signal).

9 **Sleep Button Status** ..... default = 0
This bit is set when the sleep button is pressed (SLPBTN# signal asserted low).

8 **Power Button Status** ..... default = 0
This bit is set when the PWRBTN# signal is asserted low. If the PWRBTN# signal is held low for more than four seconds, this bit is cleared, the Power Button Status bit is set, and the system will transition into the soft off state.

7-6 **Reserved** ..... always reads 0

5 **Global Status** ..... default = 0
This bit is set by hardware when the BIOS Release bit is set (typically by an SMI routine to release control of the SCI / SMI lock). When this bit is cleared by software (by writing a one to this bit position) the BIOS Release bit is also cleared at the same time by hardware.

4 **Bus Master Status** ..... default = 0
This bit is set when a system bus master requests the system bus. All PCI master, ISA master and ISA DMA devices are included.

3-1 **Reserved** ..... always reads 0

0 **ACPI Timer Carry Status** ..... default = 0
The bit is set when the 23rd (31st) bit of the 24 (32) bit ACPI power management timer changes.

I/O Offset 3-2 - Power Management Enable ..... RW

The bits in this register correspond to the bits in the Power Management Status Register at offset 1-0.

15 **Reserved** .....always reads 0

14-12 **Reserved** .....always reads 0

11 **Reserved** .....always reads 0

10 **RTC Alarm Enable** .....default = 0
This bit may be set to trigger either an SCI or an SMI (depending on the setting of the SCI Enable bit) to be generated when the RTC Status bit is set.

9 **Sleep Button Enable** .....default = 0
This bit may be set to trigger either an SCI or SMI when the Sleep Button Status bit is set.

8 **Power Button Enable** .....default = 0
This bit may be set to trigger either an SCI or an SMI (depending on the setting of the SCI Enable bit) to be generated when the Power Button Status bit is set.

7-6 **Reserved** .....always reads 0

5 **Global Enable** .....default = 0
This bit may be set to trigger either an SCI or an SMI (depending on the setting of the SCI Enable bit) to be generated when the Global Status bit is set.

4 **Reserved** .....always reads 0

3-1 **Reserved** .....always reads 0

0 **ACPI Timer Enable**.....default = 0
This bit may be set to trigger either an SCI or an SMI (depending on the setting of the SCI Enable bit) to be generated when the Timer Status bit is set.

I/O Offset 5-4 - Power Management Control.....RW

15 Soft Resume
This bit is used to allow a system using an AT power supply to operate as if an ATX power supply were being used. Refer to the BIOS Porting Guide for implementation details.
0 Disable ..... default
1 Enable

14 Reserved ..... always reads 0

13 Sleep Enable .....Write 1 to activate
This is a write-only bit; reads from this bit always return zero. Writing a one to this bit causes the system to sequence into the sleep (suspend) state defined by the Sleep Type field.

12-10 Sleep Type
000 Normal On
001 Suspend to RAM (STR)
010 Suspend to Disk (STD) (also called Soft Off). The VCC power plane is turned off while the VSUS33 and VBAT planes remain on.
011 Reserved
100 Power On Suspend without Reset
101 Power On Suspend with CPU Reset
110 Power On Suspend with CPU/PCI Reset
111 Reserved
In any sleep state, there is minimal interface between powered and non-powered planes so that the effort for hardware design may be well managed.

9 Reserved ..... always reads 0

8 STD Command Generates System Reset Only
0 Disable ..... default
1 Enable (STD command generates a system reset and not STD)

7-3 Reserved ..... always reads 0

2 Global Release ..... **WO**, default = 0
This bit is set by ACPI software to indicate the release of the SCI / SMI lock. Upon setting of this bit, the hardware automatically sets the BIOS Status bit. The bit is cleared by hardware when the BIOS Status bit is cleared by software. Note that the setting of this bit will cause an SMI to be generated if the BIOS Enable bit is set (bit-5 of the Global Enable register at offset 2Ah).

1 Bus Master Reload
This bit controls whether bus master requests (PMIO Rx00[4] = 1) transition the processor from C3 to C0 state.
0 Bus master requests are ignored by power management logic ..... default
1 Bus master requests transition the processor from the C3 state to the C0 state

0 SCI / SMI Select
This bit controls whether SCI or SMI is generated for power management events triggered by the Power Button, Sleep Button, and RTC (when PMIO Rx1-0 bits 8, 9, or 10 equal one).
0 Generate SMI..... default
1 Generate SCI
Note that certain power management events can be programmed individually to generate an SCI or SMI independent of the setting of this bit (refer to the General Purpose SCI Enable and General Purpose SMI Enable registers at offsets 22 and 24). Also, Timer Status & Global Status always generate SCI and BIOS Status always generates SMI.

I/O Offset 0B-08 - Power Management Timer ..... RW

31-24 Extended Timer Value
This field reads back 0 if the 24-bit timer option is selected (Rx41 bit-3).

23-0 Timer Value
This read-only field returns the running count of the power management timer. This is a 24/32-bit counter that runs off a 3.579545 MHz clock, and counts while in the S0 (working) system state. The timer is reset to an initial value of zero during a reset, and then continues counting until the 14.31818 MHz input to the chip is stopped. If the clock is restarted without a reset, then the counter will continue counting from where it stopped.

10 PCI Bus Clock Run Without Stop
- 0 PCKRUN# is always asserted ..... default
- 1 PCKRUN# will be de-activated after the PCI bus is idle for 26 clocks

9 Host Clock Stop
This bit controls whether CPUSTP# is asserted in C3 and S1 states. Normally CPUSTP# is not asserted in C3 and S1 states, only STPCLK# is asserted.
- 0 CPUSTP# will not be asserted in C3 and S1 states (only STPCLK# is asserted)..... default

- 0 SLP# is not asserted in C3 state ..... default
- 1 SLP# is asserted in C3 state

7 Lower CPU Voltage During C3 / S1
This bit controls whether the CPU voltage is lowered when in C3/S1 state. The voltage is lowered using the VRDSLP signal to the voltage regulator. PMIO RxE5[3] must be 0 to enable the voltage change function. Bits 8 and 9 of this register must also be set to 1.
- 0 Disable (normal voltage during C3/S1)..... def
- 1 Enable (lower voltage during C3/S1)

6-5 Reserved ..... always reads 0

4 Throttling Enable
Setting this bit starts clock throttling (modulating the STPCLK# signal) regardless of the CPU state. The throttling duty cycle is determined by bits 3-0 of this register.

3-0 Throttling Duty Cycle
This field determines the duty cycle of the STPCLK# signal when the system is in throttling mode ("Throttling Enable" bit set to one). The duty cycle indicates the percentage of performance (the lower the percentage, the lower the performance and the higher the power savings).

I/O Offset 14 - Processor Level 2.....RO

7-0 Level 2 .....always reads 0
Reads from this register put the processor into the Stop Grant state (the VT8235 asserts STPCLK# to suspend the processor). Wake up from Stop Grant state is by interrupt (INTR, SMI, and SCI).

Reads from this register return all zeros; writes to this register have no effect.

I/O Offset 15 - Processor Level 3.....RO

7-0 Level 3 .....always reads 0
Reads from this register put the processor in the C3 clock state with the STPCLK# signal asserted. If Rx10[9] = 1 then the CPU clock is also stopped by asserting CPUSTP#. Wakeup from the C3 state is by interrupt (INTR, SMI, and SCI).

Reads from this register return all zeros; writes to this register have no effect.

1 BIOS Release

This bit is set by legacy software to indicate release of the SCI/SMI lock. Upon setting of this bit, hardware automatically sets the Global Status bit. This bit is cleared by hardware when the Global Status bit cleared by software.

Note that if the Global Enable bit is set (Power Management Enable register Rx2[5]), then setting this bit causes an SCI to be generated (because setting this bit causes the Global Status bit to be set).

0 SMI Enable

I/O Offset 33-30 - Primary Activity Detect Status.....RWC

These bits correspond to the Primary Activity Detect Enable bits in Rx37-34. If the corresponding bit is set in that register, setting of a bit below will cause the Primary Activity Status (PACT_STS) bit to be set (Global Status register Rx28[0]). All bits in this register default to 0, are set by hardware only, and may only be cleared by writing 1s to the desired bit.

0 PCI Master Access Status..... (DRQ_STS)
Set on the occurrence of PCI master activity.

Note: Setting of Primary Activity Status (PACT_STS) may be done to enable a "Primary Activity Event": an SMI will be generated if the Primary Activity Enable bit is set (Global Enable register Rx2A[0]) and/or the GP0 timer will be reloaded if the "GP0 Timer Reload on Primary Activity" bit is set (GP Timer Reload Enable register Rx38[0]).

I/O Offset 00 – SMBus Host Status.....RWC

- **7 Reserved** ..... always reads 0
- **6 SMB Semaphore.....RWC**
  This bit is used as a semaphore among various independent software threads that may need to use the Host SMBus logic and has no effect on hardware. After reset, this bit reads 0. Writing 1 to this bit causes the next read to return 0, then all reads after that return 1. Writing 0 to this bit has no effect. Software can therefore write 1 to request control and if readback is 0 then it will own usage of the host controller.

1 Start Execution of Command

Writing a 1 to this bit causes the SMBus controller host interface to initiate execution of the command programmed in the SMBus Command Protocol field (bits 4-2). All necessary registers should be programmed prior to writing a 1 to this bit. The Host Busy bit (SMBus Host Status Register bit-0) can be used to identify when the SMBus controller has completed command execution.

7-0 SMBUS Data 1.....default = 0

I/O Offset 07h – SMBus Block Data..... RW

Reads and writes to this register are used to access the 32-byte block data storage array. An internal index pointer is used to address the array. It is reset to 0 by reads of the SMBus Host Control register (I/O Offset 2) and incremented automatically by each access to this register. The transfer of block data into (read) or out of (write) this storage array during an SMBus transaction always starts at index address 0.

4 Current SGD Index Equals Stop Index ..... RO
- 0 SGD index not equal to stop index..... default
- 1 SGD index being processed equals the stop index. This bit differs from bit-2 of this register in that this bit becomes 1 as soon as the SGD *reaches* the index equal to the stop index. Bit-2 becomes 1 after the SGD *finishes processing* the index equal to the stop index. So this bit will always turn on before bit-2.

3 SGD Trigger Queued ..... RO

This bit reports whether the trigger used to restart the SGD operation is queued (I/O Offset 71[1] = 1 while the SGD engine is running).
- 0 SGD trigger not queued..... default

FUNCTIONAL DESCRIPTIONS

Power Management

Power Management Subsystem Overview

The power management function of the VT8235 is indicated in the following block diagram:

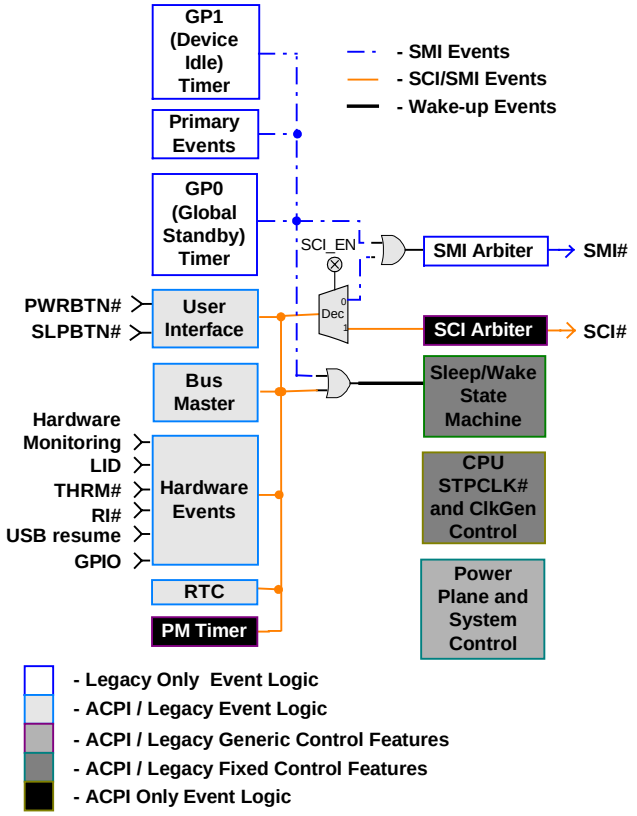

Figure 3. Power Management Subsystem Block Diagram

Refer to ACPI Specification v2.0 and APM specification v1.2 for additional information.

Processor Bus States

The VT8235 supports the complete set of C0 to C3 processor states as specified in the Advanced Configuration and Power Interface (ACPI) specification (and defined in ACPI I/O space Registers 10-15):

C0: Normal Operation

C1: CPU Halt (controlled by software).

C2: Stop Clock. Entered when the Processor Level 2 register (PMIO Rx14) is read. The STPCLK# signal is asserted to put the processor in the Stop Grant State. The CPUSTP# signal is not asserted so that host clocks remain running. To exit this state, the chip negates STPCLK#.

C3: Suspend. Entered when the Processor Level 3 register (PMIO Rx15) is read. In addition to STPCLK# assertion as in the C2 state, the SUSST1# (suspend status 1) signal is asserted to tell the north bridge to switch to "Suspend DRAM Refresh" mode based on the 32KHz suspend clock (SUSCLK) provided by the VT8235. If the Host Stop bit is enabled, then CPUSTP# is also asserted to stop clock generation and put the CPU into Stop Clock State. To exit this state, the chip negates CPUSTP# and allows time for the processor PLL to lock. Then the SUSST1# and STPCLK# signals are negated to resume to normal operation.

During normal operation, two mechanisms are provided to modulate CPU execution and control power consumption by throttling the duty cycle of STPCLK#:

a. Setting the Throttle Enable bit to 1, the duty cycle defined in Throttle Duty Cycle (PMIO Rx10) is used.

b. THRM# pin assertion enables automatic clock throttling with duty cycle pre-configured in THRM# Duty Cycle (PCI configuration Rx4C).

System Suspend States and Power Plane Control

There are three power planes inside the VT8235. The first power plane (VSUS33) is always on unless turned off by the mechanical switch. The second power plane (VCC) is controlled by chip output SUSC# (also called "PSON"). The third plane (VCCRTC) is powered by the combination of the VSUS33 and the external battery (VBAT) for the integrated real time clock. Most of the circuitry inside the VT8235 is powered by VCC. The amount of logic powered by VSUS33 is very small; its main function is to control the supply of VCC and other power planes. VCCRTC is always on unless both the mechanical switch and VBAT are removed.

The VT8235 supports multiple system suspend states by configuring the SLP_TYP field of ACPI I/O space register Rx4-5:

a) **POS (Power On Suspend):** Most devices in the system remain powered. The host bus is put into an equivalent of the C3 state. In particular, the CPU is put into the Stop Grant State or Stop Clock State depending on the setting of the Host Stop bit. SUSST1# is asserted to tell the north bridge to switch to "Suspend DRAM Refresh" mode based on the 32KHz SUSCLK provided by the VT8235. As to the PCI bus, setting the PCLK Run bit to 0 enables the CLKRUN protocol defined in the PCI Mobile Design Guide. That is, the PCKRUN# pin will be de-activated after the PCI bus is idle for 26 clocks. Any PCI bus masters including the north bridge may resume PCI clock operation by pulling the PCKRUN# pin low. During the PCKRUN# de-activation period, the PCISTP# pin may be activated to disable the output of the PCI clock generator if the PCI_STP bit is enabled. When the system resumes from POS, the VT8235 can optionally resume without resetting the system, can reset the processor only, or can reset the entire system. When no reset is performed, the chip only needs to wait for the clock synthesizer and processor PLL to lock before the system is resumed, which typically takes 20ms.

b) **STR (Suspend to RAM):** Power is removed from most of the system except the system DRAM. Power is supplied to the suspend refresh logic in the north bridge (e.g., VSUS25 of the VT8633) and the suspend logic of the VT8235 (VSUS33).

c) **STD (Suspend to Disk, also called Soft-off):** Power is removed from most of the system except the suspend logic of VT8235 (VSUS33).

d) **Mechanical Off:** This is not a suspend state. All power in the system is removed except the RTC battery.

The suspend state is entered by setting the Sleep Enable bit to 1. Three power plane control signals (SUSA#, SUSB# and SUSC#) are provided to turn off more system power planes as the system moves to deeper power-down states, i.e., from normal operation to POS (only SUSA# asserted), to STR (both SUSA# and SUSB# asserted), and to STD (all three SUS# signals asserted). In particular, the assertion of SUSC# can be used to turn off the VCC supply to the VT8235.

One additional suspend status indicator (SUSST1#) is provided to inform the north bridge and the rest of the system of the processor and system suspend states. SUSST1# is asserted when the system enters the suspend state or the processor enters the C3 state. SUSST1# is connected to the north bridge to switch between normal and suspend-DRAM-refresh modes.

General Purpose I/O Ports

As ACPI compliant hardware, the VT8235 includes PWRBTN#, SLPBTN#, and RI# pins to implement power button, sleep button, and ring indicator functionality, respectively. Furthermore, the VT8235 offers many general-purpose I/O ports with the following capabilities:

- **I^2C / SMB Support**
- **Thermal Detect**
- **Notebook Lid Open / Close Detect**
- **Battery Low Detect**
- **Twelve General Purpose Input Ports** (multiplexed with other functions).
- **Nineteen General Purpose Output Ports** (1 dedicated and 18 multiplexed with other functions)
- **Four General Purpose Input / Output Ports** (multiplexed with other functions)

In addition, the VT8235 provides an external dedicated SMI pin (EXTSMI#). The external SMI input can be programmed to trigger an SCI or SMI at both the rising and falling edges of the corresponding input signal. Software can check the status of the input pin and take appropriate actions.

Power Management Events

Three types of power management events are supported:

1) **ACPI-required Fixed Events** defined in the PM1a Status and PM1a Enable registers. These events can trigger either SCI or SMI depending on the SCI Enable bit:
   - PWRBTN# Triggering
   - RTC Alarm
   - Sleep Button
   - ACPI Power Management Timer Carry (always SCI)
   - BIOS Release (always SCI)
2) **ACPI-aware General Purpose Function Events** defined in the GP Status and GP SCI Enable, and GP SMI Enable registers. These events can trigger either SCI or SMI depending on the setting of individual SMI and SCI enable bits:
   - External SMI triggering
   - USB Resume
   - Ring Indicator (RI#)
   - Battery Low Detect (BATLOW#)
   - Notebook Lid Open/Close Detect (LID)
   - Thermal Detect (THRM#)
3) **Generic Global Events** defined in the Global Status and Global Enable registers. These registers are mainly used for SMI:
   - PCI Bus Clock Run Resume
   - Primary Interrupt Occurance
   - GP0 and GP1 Timer Time Out
   - Secondary Event Timer Time Out
   - Occurrence of Primary Events

     (defined in the Primary Activity Status and Primary Activity Enable registers)
   - Legacy USB accesses (keyboard and mouse)
   - Software SMI

System and Processor Resume Events

Depending on the system suspend state, different features can be enabled to resume the system. There are two classes of resume events:

a) VSUS-based events. Event logic resides in the VSUS plane and thus can resume the system from any suspend state. Such events include PWRBTN#, RI#, BATLOW#, LID, SMBus resume event, RTC alarm, EXTSMI#, and GP1 (EXTSMI1#).

b) VCC-Based Events. Event logic resides in the VCC plane and thus can only resume the system from the POS state. Such events include the ACPI PM timer, USB resume, and EXTSMIn#.

Legacy Power Management Timers

In addition to the ACPI power management timer, the VT8235 includes the following four legacy power management timers:

GP0 Timer: general purpose timer with primary event

GP1 Timer: general purpose timer with peripheral event reload

Secondary Event Timer: to monitor secondary events

Conserve Mode Timer: Hardware-controlled return to standby

The normal sequence of operations for a general purpose timer (GP0 or GP1) is to

1) First program the time base and timer value of the initial count (register GP Timer Count).
2) Then activate counting by setting the GP0 Start or GP1 Start bit to one: the timer will start with the initial count and count down towards 0.
3) When the timer counts down to zero, an SMI will be generated if enabled (GP0 Timeout Enable and GP1 Timeout Enable in the Global Enable register) with status recorded (GP0 Tomeout Status and GP1 Timeout Status in the Global Status register).
4) Each timer can also be programmed to reload the initial count and restart counting automatically after counting down to 0. This feature is not used in standard VIA BIOS.

The GP0 and GP1 timers can be used just as the general purpose timers described above. However, they can also be programmed to reload the initial count by system primary events or peripheral events thus used as primary event (global standby) timer and peripheral timer, respectively. The secondary event timer is solely used to monitor secondary events.

System Primary and Secondary Events

Primary system events are distinguished in the Primary Activity Status and Primary Activity Enable registers:

Bit	Event	Trigger
7	**Keyboard Access**	I/O port 60h
6	**Serial Port Access**	I/O ports 3F8h-3FFh, 2F8h-2FFh, 3E8h-3EFh, or 2E8h-2EFh
5	**Parallel Port Access**	I/O ports 378h-37Fh or 278h-27Fh
4	**Video Access**	I/O ports 3B0h-3DFh or memory A/B segments
3	**IDE/Floppy Access**	I/O ports 1F0h-1F7h, 170h-177h, or 3F5h
2	**Reserved**	
1	**Primary Interrupts**	Each channel of the interrupt controller can be programmed to be a primary or secondary interrupt
0	**ISA Master/DMA Activity**	

Each category can be enabled as a primary event by setting the corresponding bit of the Primary Activity Enable register to 1. If enabled, the occurrence of the primary event reloads the GP0 timer if the Primary Activity GP0 Enable bit is also set to 1. The cause of the timer reload is recorded in the corresponding bit of Primary Activity Status register while the timer is reloaded. If no enabled primary event occurs during the count down, the GP0 timer will time out (count down to 0) and the system can be programmed (setting the GP0 Timeout Enable bit in the Global Enable register to one) to trigger an SMI to switch the system to a power down mode.

The VT8235 distinguishes two kinds of interrupt requests as far as power management is concerned: the primary and secondary interrupts. Like other primary events, the occurrence of a primary interrupt demands that the system be restored to full processing capability. Secondary interrupts, however, are typically used for housekeeping tasks in the background unnoticeable to the user. The VT8235 allows each channel of interrupt request to be declared as either primary, secondary, or ignorable in the Primary IRQ Channel and Secondary IRQ Channel registers. Secondary interrupts are the only system secondary events defined in the VT8235.

Like primary events, primary interrupts can be made to reload the GP0 timer by setting the PIRQ Enable bit to 1. Secondary interrupts do not reload the GP0 timer. Therefore the GP0 timer will time out and the SMI routine can put the system into power down mode if no events other than secondary interrupts are happening periodically in the background.

Primary events can be programmed to trigger an SMI (setting of the Primary Activity Enable bit). Typically, this SMI triggering is turned off during normal system operation to avoid degrading system performance. Triggering is turned on by the SMI routine before entering the power down mode so that the system may be returned to normal operation at the occurrence of primary events. At the same time, the GP0 timer is reloaded and the count down process is restarted.

Peripheral Events

Primary and secondary events define system events in general and the response is typically expressed in terms of system events. Individual peripheral events can also be monitored by the VT8235 through the GP1 timer. The following four categories of peripheral events are distinguished (via the GP Reload Enable register):

Bit-7 **Keyboard Access**
Bit-6 **Serial Port Access**
Bit-4 **Video Access**
Bit-3 **IDE/Floppy Access**

The four categories are subsets of the primary events as defined in Primary Activity Enable and the occurrence of these events can be checked through a common register Primary Activity Status. As a peripheral timer, GP1 can be used to monitor one (or more than one) of the above four device types by programming the corresponding bit to one and the other bits to zero. Time out of the GP1 timer indicates no activity of the corresponding device type and appropriate action can be taken as a result.
